

Notes

In Sect. 1, some previously unpublished details of the substitution method used are described that concern both the substitution densimeter itself and the preparation of the water reference. Although these topics were addressed in the discussion and found to be worthy of mention, they relate to our article on the substitution method³ and are beyond the scope of this article, wherefore they are found here.

In Sect. 2, the data used to develop and validate the density–salinity relation is tabulated. For practicability, an .mht- and an .xlsx-file containing the data are attached to this supplement. Uncertainties are given either as combined uncertainties, u , with corresponding degrees of freedom, or as uncertainties for a probability of 95.45 %, U , in accordance with the JCGM ‘Guide to the Expression of Uncertainty in Measurement’ of 2008.

Previously unpublished details related to ‘A method to measure the density of seawater accurately to the level of 10⁻⁶

Impact of heavy isotope enrichment on density caused by evaporation

Ultrapure water was used as a density reference in the substitution measurements. To remove the air dissolved in it, it was boiled without refeeding the vapour. Since the frequency of the (heavy) isotopes deuterium, oxygen-17, and oxygen-18 is higher in the liquid than in the vapour, heavy isotopes accumulate in the liquid during evaporation, thereby increasing the water density. By a simple theoretical approach, the impact on the water density is quantified. The results suggest that the water density changes insignificantly in moderate boiling and, additionally, that evaporation at low temperatures causes higher density changes than evaporation at high temperatures.

If a flask contains a very small vapour (*v*) compared to a liquid phase (*l*) each consisting of water, and the water contains ¹H and ²H, or D, atoms and ¹⁶O, ¹⁷O, and ¹⁸O atoms, then the frequency of these atoms in the liquid and vapour is different. The frequency of an isotope in the liquid relative to that in the vapour is described by means of the isotopic fractionation factor α , which is for deuterium:

$$\alpha_D = \frac{n_D^l / n_H^l}{n_D^v / n_H^v},$$

where *n* is the amount-of-substance. For example, n_D^l is the amount-of-substance deuterium in the liquid. The fractionation factor is temperature-dependent⁴.

If a very small amount is repeatedly removed from the vapour at very long intervals, some molecules from the liquid „vaporize“ at (almost) constant temperature. The infinitesimal changes in the H- and D-amount-of-substance in the liquid and vapour are then linked by $dn_D^v = -dn_D^l$ and $dn_H^v = -dn_H^l$. For the ratio D to H of the vapour, it follows that $n_D^v / n_H^v \approx dn_D^l / dn_H^l$. Inserting this formula into above formula, transforming and integrating from the beginning (I) to the end of vaporization (II) results in:

$$\frac{n_D^{II}}{n_D^I} = \sqrt{\frac{n_H^{II}}{n_H^I}},$$

where all amount-of-substances refer to the liquid.

The isotopic composition of deuterium and oxygen-18 in water is given by isotopic abundances relative to VSMOW, δ_D and δ_{18} , see article. The use of the isotopic abundance instead of the amount-of-substance in above formula yields:

$$\frac{\delta_D^{II} + 1}{\delta_D^I + 1} = \left(\frac{n_H^{II}}{n_H^I} \right)^{\frac{1-\alpha_D}{\alpha_D}}.$$

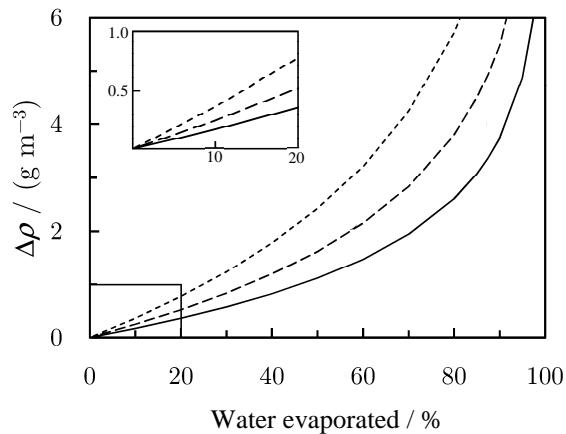

For oxygen the formula is similar.

⁴ Horita, J. and Wesolowski, D. J.: Liquid-vapor fractionation of oxygen and hydrogen isotopes of water from the freezing to the critical temperature, Geochimica et Cosmochimica Acta, 58, 16, 3425–37, doi:10.1016/0016-7037(94)90096-5, 1994.

The density change caused by the accumulation of deuterium, oxygen-17 and -18 can be calculated using the formula of Girard and Menaché⁵ that is given in appendix A of the article.

The change in density of water caused by boiling is shown in the figure below. If 10 % of the liquid water vaporize in boiling, then the density increases by a maximum of 0.3 g m^{-3} independent of the temperature, thereby suggesting that, in moderate boiling, heavy isotopes accumulate insignificantly in the liquid in terms of the density uncertainty of 2 g m^{-3} .

Figure. Density increase of water, $\Delta\rho$, due to isotope enrichment during boiling. Calculated curves for vapourization into a pure water vapour phase at 20°C (---), 60°C (—) and 100°C .

Impact of glass dissolution on water density caused by boiling in a borosilicate flask

The ultrapure water used as water reference in the substitution measurements was boiled for degassing in a 1 L-Duran borosilicate glass flask. A test of the hydrolytic resistance of Duran according to ISO 719, in which 2 g glass powder with a grain diameter of 0.4 mm to 0.6 mm is exposed to 50 mL of water at 98°C , results in a sodium molality of 0.1 nmol kg^{-1} after 1 hour⁶. If this molality is converted from the glass powder surface to the Duran flask surface, then this results in a density increase $\ll 0.1 \text{ g m}^{-3}$. Since ISO 719 test does not take into account the solubility of all glass components, it is sometimes considered insufficient⁷.

A different test of the hydrolytic resistance of 10 mL borosilicate glass ampoules with a composition of 75 % SiO_2 , 11 % B_2O_3 , 7 % Na_2O und 5 % Al_2O_3 at 121°C yielded silicon molalities up to $6.4 \mu\text{mol kg}^{-1}$ after 60 min⁸. If this molality is converted from the surface of the 10 mL glass flask to that of the Duran flask, then a molality of $1.4 \mu\text{mol kg}^{-1}$ results corresponding to an increase in density of 0.08 g m^{-3} . Other borosilicate glass ampoules containing 70 % SiO_2 , on the other hand, caused an increase in density of only 0.04 g m^{-3} . A linear SiO_2 -amount-of-substance dependence suggests an increase

⁸ Bohrer, D., Bortoluzzi, F., Nascimento, P. C., Carvalho, L. M. and Ramirez, A. G.: Silicate release from glass for pharmaceutical preparations, International Journal of Pharmaceutics, 355, 174–183, doi:10.1016/j.ijpharm.2007.12.025, 2008.

in density of 0.16 g m^{-3} for Duran (with 80 % SiO₂). The glass dissolution increases exponentially with temperature⁹, so that, after conversion to the water boiling temperature of 100 °C, a density increase of $< 0.1 \text{ g m}^{-3}$ is yielded for the water that, for degassing, was boiled in the 1 L-Duran flask. This shows that the increase in density can be neglected, but also that the water must not boil much longer in borosilicate flasks, because otherwise its density increases significantly compared to the density uncertainty of 2 g m^{-3} .

Impact of a densimeter zero-drift on the accuracy of a seawater substitution density

Any densimeter tends to drift significantly sooner or later, wherefore regular calibration and appropriate adjustment is necessary to yield consistent results. Vibrating-tube densimeters (VTDs) are quick-adjusted using air and water. The drift of a vibrating tube made of glass can be different for air and water. Therefore, the drift is not completely corrected, if seawater substitution measurements are conducted using a water reference. A theoretical approach is used to quantify the zero-drift impact on the (seawater) substitution density, which is similar to that for air. The results suggest that the deviation in the substitution density is insignificant, if the densimeter is adjusted regularly.

The VTD used in the substitution measurements is a DMA 5000 M that is adjusted by the manufacturer. The standards used for this purpose are multiple reference fluids (including air and water), whereof the density and viscosity are known, respectively. A quick-adjustment is provided to the customer using air and water. We performed a quick-adjustment before any substitution measurement.

For the calculation of air density, the formula given by Spieweck and Bettin¹⁰ for a relative humidity of 50 % is used by the internal firmware of the device¹¹. The air pressure is either measured by an internal barometer or provided by the customer. We used an external high precision barometer that was calibrated to provide the air pressure. The DMA 5000 M manual¹¹ also contains data tables. The formula given by Spieweck and Bettin deviates significantly less than 1 g m^{-3} for 20 °C and 50 %rh from the recent formulation of air density CIPM-2007¹². A change in relative humidity of 10 % at 20 °C changes the air density by 1 g m^{-3} .

The impact of a densimeter zero-drift, or deviation in air density, on the substitution density can be estimated using the formula:

$$\Delta\rho_{\text{SW}} = (1 - \gamma) \cdot \Delta\rho_A + \gamma \cdot \Delta\rho_{\text{H}_2\text{O}} \quad \text{with } \gamma = (\rho_{\text{SW}} - \rho_A) / (\rho_{\text{H}_2\text{O}} - \rho_A),$$

where ρ_A and $\Delta\rho_A$ are the air reference density and deviation therefrom (ref. minus meas.), $\rho_{\text{H}_2\text{O}}$ and $\Delta\rho_{\text{H}_2\text{O}}$ are the water reference density and deviation therefrom (ref. minus meas.), and $\Delta\rho_{\text{SW}}$ is the difference between substitution and measured seawater density (subs. minus meas.).

The idea behind the formula is illustrated in (and may be derived from) the figure below.

Figure. Linear characteristic curve of an ideal densimeter (—) and of a densimeter with a zero-offset (---).

A maximum deviation in air density of 20 g m^{-3} (ref. minus meas.) without a deviation in water density causes a non-considered deviation in the substitution density of seawater with salinity 35 of 0.5 g m^{-3} . If, additionally, there is a maximum deviation in water density of -10 g m^{-3} (in the opposite direction), then a non-considered deviation in the substitution density of 0.8 g m^{-3} results. However, we never saw such deviations during our substitution measurements. Additionally, such deviations are random, and are therefore considered in the repeatability of a substitution measurement, which for our measurements at atmospheric pressure was 1 g m^{-3} . Therefore, the impact is negligible, provided that the densimeter is regularly quick-adjusted by the user, which is usual in a well-managed lab.

Impact of U-tube-input assembly on the seawater density

Measuring the density not using the substitution method. Shortly after a quick-adjustment, even if the densimeter was filled manually using syringes that were directly and coarsely connected to the inlet of the oscillating U-tube, we never observed deviations $> \pm 5 \text{ g m}^{-3}$. The inlet may be mechanically decoupled to avoid such deviations.

Measuring the density using the substitution method (and a permanent filling installation). Such impacts are eliminated, as the impact on the measurement of water and seawater density is identical and no parts are being moved during the measurements. The density is determined from the oscillation frequency and has to be corrected for damping effects that are caused by the friction between fluid layers due to viscosity. To correct for this effect, the first harmonic oscillation frequency is used by the firmware¹³. The impact of the input assembly on density measurement therefore has to be considered before this background. Frankly speaking, the damping-corrected density has to be used instead of the non-damping-corrected density. Using the non-damping-corrected density in a substitution measurement of seawater can cause the density being measured too high by up to 10 g m^{-3} , if syringes are used for filling, and 2 g m^{-3} to 3 g m^{-3} , even if a permanent installation is used for filling, as damping effects force the base frequency being too low, i.e. the oscillation period too long, thereby pretending a higher density.

¹³ Stabinger, H.: Density measurement using modern oscillating transducers, South Yorkshire Trading Unit, Sheffield, 1994.

Impact of densimeter inclination on the seawater substitution density

The impact of a (post-adjustment) densimeter inclination on the measurement density is 1.82 g m^{-3} per 1° . Apart from the fact that the DMAs used to measure the seawater density were set up on fixed straight surfaces, such deviations are corrected by the substitution method. If a DMA is used without the substitution method, it can also be quick-adjusted at an inclination and then used afterwards. The decisive factor is that the inclination does not change between adjustment and measurement. This may be a problem in measurements aboard ship.

Avoidance of oil diffusion into the U-tube of the DMA HP during measurements at high pressure

In the substitution densimeter for high pressures, oil is used to prevent corrosion of the pressure sensors. For reasons of accuracy, no pressure diaphragm was used. Oil and water were therefore in direct contact.

Oil and water are not miscible, so there is always a phase boundary between both liquids. The phase boundary is reinforced, as the capillary tube in which both liquids meet has a small diameter of 1.6 mm. The density of the oil is lower than that of the water. Advantage was taken of that by installing the density measurement part at a lower level than the pressurization part that is filled with oil, thereby preventing convection downwards (into the DMA).

After each substitution measurement, the filling line was rinsed with ethanol and water and thoroughly dried using filtered dry air, thereby removing any oil that may stick to and creep on the inner tube wall, as such oil remains can disturb a clean replacement of seawater by water and vice versa. If, nonetheless, there is such a disturbance, this was seen in an increase in the water density or decrease in the seawater density measured, provided a measurement series is conducted, i.e. water – seawater – water – seawater – ... – water. For the high pressure measurements, we performed usually 5 repeated substitution measurements per temperature-pressure density point, i.e. 11 liquid replacements (water was always first and last); obeying the cleaning routine, replacement of liquids that were accompanied by impurities never occurred.
